

What is a solar power satellite?

In the 1960s research in the fields of solar energy conversion technology and space technology led to the concept of the solar power satellite (SPS) to beam power from space to Earth. As conceived, the SPS would convert solar energy into electricity and feed it to microwave generators forming part of a planar, phased-array transmitting antenna.

What are space-based solar power satellites (SPS)?

Space-based solar power satellites (SPS) are large structures in space that convert solar energy into a form of energy that is transmitted wirelessly (WPT) to any remote receiver station.

How is solar energy collected in space-based solar power?

In space-based solar power, solar energy is collected in space, which is then transmitted as a microwave or laser beam to the ground and converted into electrical energy. The idea of space-based solar power predates the space age.

How much electricity does a satellite produce?

The baseline satellite concept produces about 10 GW of electrical power on the Earth, using a large (10 km by 15 km) solar array located in geosynchronous orbit.

Can a solar power satellite meet future energy demands?

The potential of the solar power satellite (SPS) to meet future energy demands is being recognized and plans for its development are being studied. The results of extensive SPS system studies have confirmed that there are no known technical barriers to the design, deployment, or operation of the SPS.

Can a space-based solar power satellite be launched into space?

One of the main challenges for any space-based solar power satellite is the construction of large structures in orbit. This requires significant amounts of material to be launched into space, which will need to be assembled, maintained, and possibly replaced over time.
